

In the Specification:

The Paragraph beginning on page 15, line 17 is amended as follows:

When an image designer is using server 190 to design a prioritized image, some testing of the prioritization will usually be performed. Selecting and assigning priorities to portions of an image will usually be an iterative process: the image designer selects one or portions of an image, assigns these portions a priority, saves the image in a prioritized image file, and then simulates receiving the image to ensure that the prioritization is as the image designer imagined and wants it to be. In this regard, simulation browser 187 ~~186~~, shown in the example of FIG. 1 as displaying an image 187, is used to test the prioritization scheme performed on image 197. A general-purpose browser could also perform this function; however, because the image will load so quickly if the image is on the server, a time delay is usually required to simulate reception of a prioritized image. Simulation browser 186 can add a time delay between prioritized portions of an image to more adequately indicate how the prioritized file will really be seen by a user.
